

# Compilation and Program Analysis (#9a) : Functions: semantics

Ludovic Henrio

Master 1, ENS de Lyon et Dpt Info, Lyon1

2021-2022

# Approach and objective of the course

- Give a semantics to functions in an imperative setting.  
inspired by what can be found in the literature
- Explore the different ways to deal with variables, different environments of execution, ...
- Big step and small step operational semantics
- Observe that things are more complex but also more constructive than with a functional calculus like  $\lambda$ -calculus.

## Note on organisation:

1: Course + **live proofs** ;

2: **exercises and proofs done after the course**

- 1 Operational Semantics for functions
  - Big-step semantics: first solution
  - Big-step semantics: second solution
  - Big-step semantics: third solution
  - Small-step semantics based on third solution
- 2 Safety of the type-system

# Mini-While Syntax 1/2

Expressions:

$$e ::= c \mid e + e \mid e \times e \mid \dots$$

Mini-while:

$S(Smt) ::=$	$x := expr$	assign
	$  \quad x := f(e_1, \dots, e_n)$	simple function call
	$  \quad skip$	do nothing
	$  \quad S_1; S_2$	sequence
	$  \quad \text{if } b \text{ then } S_1 \text{ else } S_2$	test
	$  \quad \text{while } b \text{ do } S \text{ done}$	loop

## Mini-While Syntax 2/2

**[NEW]** Programs with function definitions and global variables

$Prog ::= D \text{ FunDef } Body$	Program
$Body ::= D; S$	Function/main body
$D ::= \text{var } x : \tau   D; D$	Variable declaration
$FunDef ::= \tau \text{ } f(x_1 : \tau_1, \dots, x_n : \tau_n) \text{ } Body; \text{return } e$	Function def
$\quad   \text{ FunDef } FunDef$	

Note/discussion: to simplify, function call is not an expression but a special statement. return only appears at the end of the function definition.

## Dealing with variable declaration and store management

Variable declaration:  $Vars(D)$  is the set of variables declared by  $D$ .

Reminder: we could use it to initialize the local memory when needed and ensure progress (see typing course).

We define a global store update:

$$\begin{array}{ll} \sigma'[X \mapsto \sigma](x) = \sigma(x) & \text{if } x \in X \\ \sigma'(x) & \text{else} \end{array}$$

This will be used to restore part of the store to a previous value.

## Function table

For each function declared with name  $f$  we have  $params(f)$  the list of parameter variables,  $ret(f)$  the expression in the return statement, and  $body(f)$  the function body.

This could be formally defined as a function table  $\Phi$  that is given as parameter of the semantics, i.e.: change the signature into  $\Phi \vdash (S, \sigma) \longrightarrow \sigma'$  and use  $\Phi$  to obtain  $ret(f)$ ,  $params(f)$ , and  $body(f)$ .

Here we suppose that the functions  $ret$ ,  $params$  and  $body$  are globally known.

# Big step semantics (old) 1/2

$$\longrightarrow: Stm \rightarrow (State \rightarrow State)$$

$$(x := e, \sigma) \longrightarrow \sigma[x \mapsto Val(e, \sigma)]$$

$$(skip, \sigma) \longrightarrow \sigma$$

$$\frac{(S_1, \sigma) \longrightarrow \sigma' \quad (S_2, \sigma') \longrightarrow \sigma''}{((S_1; S_2), \sigma) \longrightarrow \sigma''}$$

## Big step semantics (old) 2/2

$$\frac{Val(b, \sigma) = tt \quad (S_1, \sigma) \longrightarrow \sigma'}{(if\ b\ then\ S_1\ else\ S_2, \sigma) \longrightarrow \sigma'}$$

$$\frac{Val(b, \sigma) = ff \quad (S_2, \sigma) \longrightarrow \sigma'}{(if\ b\ then\ S_1\ else\ S_2, \sigma) \longrightarrow \sigma'}$$

$$\frac{Val(b, \sigma) = tt \quad (S, \sigma) \longrightarrow \sigma' \quad (while\ b\ do\ S\ done, \sigma') \longrightarrow \sigma''}{(while\ b\ do\ S\ done, \sigma) \longrightarrow \sigma''}$$

$$\frac{Val(b, \sigma) = ff}{(while\ b\ do\ S\ done, \sigma) \longrightarrow \sigma}$$

**Evaluation of program:** Let  $D \text{ FunDef } D'; S$  be a program, its evaluation is  $\sigma'$  s.t.  $(S, \emptyset) \longrightarrow \sigma'$

## 1 Operational Semantics for functions

- Big-step semantics: first solution
- Big-step semantics: second solution
- Big-step semantics: third solution
- Small-step semantics based on third solution

## 2 Safety of the type-system

# Big step semantics (NEW) – First solution

Heavy manipulation of stores:

$$\frac{\begin{array}{c} \text{body}(f) = D_f; S_f \\ \text{bind}_1(f, e_1..e_n, \sigma) = (S, \sigma') \quad (S, \sigma') \longrightarrow \sigma'' \quad v = \text{Val}(\text{ret}(f), \sigma'') \end{array}}{(x := f(e_1, \dots, e_n), \sigma) \longrightarrow \sigma''[(\text{Vars}(D_f) \cup \text{params}(f)) \mapsto \sigma, x \mapsto v]}$$

$$\text{bind}_1(f, e_1..e_n, \sigma) = (S_f, \sigma[x_1 \mapsto v_1..x_n \mapsto v_n])$$

where

$$\text{body}(f) = D_f; S_f \quad \text{params}(f) = [x_1..x_n] \quad \forall i \in [1..n]. \text{Val}(e_i, \sigma) = v_i$$

Notes:

- call-by-value,
- parameters in store,
- Non-trivial store restoration.

# An example

**Evaluate the following program:**

```
int x
int f(int x) {
  int y;
  x:=1;
  y:=2;
  return x+1;
}
{
  int y;
  x:=0;
  y:=0;
  y:=f(3);
}
```

## Evaluation of this first solution

**Variables:** What happens with variables that have the same name? local vs. local? global vs. local? recursive invocations? **discussion live**

**Problem:**  $\sigma'[(Vars(D_f) \cup params(f)) \mapsto \sigma]$  is used to restore the store as it was before the invocation.

This is really impractical: difficult to compute, difficult to reason about, far from any implementation.

But not much changes to the other rules, the initial configuration is unchanged.

## 1 Operational Semantics for functions

- Big-step semantics: first solution
- **Big-step semantics: second solution**
- Big-step semantics: third solution
- Small-step semantics based on third solution

## 2 Safety of the type-system

# Big step semantics (NEW) – Second solution

Renaming and fresh variables:

$$\frac{\text{bind}_2(f, e_1..e_n, \sigma) = (S', \sigma', e) \quad (S', \sigma') \longrightarrow \sigma'' \quad v = \text{Val}(e, \sigma'')}{(x := f(e_1, .., e_n), \sigma) \longrightarrow \sigma''[x \mapsto v]}$$

$$\text{bind}_2(f, e_1..e_n, \sigma) = (S'_f, \sigma[z_1 \mapsto v_1..z_n \mapsto v_n], e)$$

where

$$\text{body}(f) = D_f; S_f \quad \text{params}(f) = [x_1..x_n] \quad \text{Vars}(D_f) = \{y_1..y_k\}$$

$$\forall i \in [1..n]. z_i \text{ fresh} \quad \forall i \in [1..k]. t_i \text{ fresh} \quad \forall i \in [1..n]. \text{Val}(e_i, \sigma) = v_i$$

$$S'_f = S_f[z_1/x_1]..[z_n/x_n][t_1/y_1]..[t_k/y_k] \quad e = \text{ret}(f)[z_1/x_1]..[z_n/x_n][t_1/y_1]..[t_k/y_k]$$

and fresh means not in  $\sigma$  (and not among the other fresh variables)

# An example

**Evaluate the following program:**

```
int x
int f(int x) {
  int y;
  x:=1;
  y:=2;
  return x+1;
}
{
  int y;
  x:=0;
  y:=0;
  y:=f(3);
}
```

## Evaluation of this Second solution

**Variables:** The store grows (unbounded) but we could easily remove useless variables,

**Problem:** variable substitution difficult and inefficient (more difficult if recursive blocks). But no complex store manipulation.

## 1 Operational Semantics for functions

- Big-step semantics: first solution
- Big-step semantics: second solution
- **Big-step semantics: third solution**
- Small-step semantics based on third solution

## 2 Safety of the type-system

## Big step semantics (NEW) – Third solution (1/2)

A store and a stack:  $\longrightarrow: Stm, Stack, Store \rightarrow Stack, Store$

Where  $Stack: Var \rightarrow address$  and  $Store: address \rightarrow Val$

$$\frac{\begin{array}{l} bind_3(f, e_1..e_n, \Sigma, sto) = (S', \Sigma', sto') \\ (S', \Sigma', sto') \longrightarrow (\Sigma'', sto'') \quad v = Val(ret(f), sto'' \circ \Sigma'') \end{array}}{(x := f(e_1, .., e_n), \Sigma, sto) \longrightarrow (\Sigma, sto''[\Sigma(x) \mapsto v])}$$

$bind_3(f, e_1..e_n, \Sigma, sto) = (S_f, \Sigma', sto[\ell_1 \mapsto v_1.. \ell_n \mapsto v_n])$  where

$body(f) = D_f; S_f \quad params(f) = [x_1..x_n] \quad Vars(D_f) = \{y_1..y_k\} \quad \ell_1.. \ell_n$  fresh

$\ell'_1.. \ell'_k$  fresh  $\forall i \in [1..n]. Val(e_i, sto \circ \Sigma) = v_i \quad \Sigma' = \Sigma[x_1..x_n \mapsto \ell_1.. \ell_n][y_1..y_k \mapsto \ell'_1.. \ell'_k]$

where fresh means location not in  $sto$  (and not among the other fresh locations picked)

**!! Access to store must be changed everywhere. See next slide!!**

## Big step semantics (NEW) – Third solution (2/2)

We now have to deal with two levels for memory addressing, this modifies the whole semantics:  $Val(e_i, \Sigma)$  replaced by  $Val(e_i, sto \circ \Sigma)$  everywhere.

And we have a new assign rule:  $(x := e, \Sigma, sto) \longrightarrow \Sigma, sto[\Sigma(x) \mapsto Val(e, sto \circ \Sigma)]$

- the stack is “unstacked” after method invocation.
- in  $\Sigma' = \Sigma[x_1 \mapsto \ell_1..x_n \mapsto \ell_n]...$ ,  $\Sigma$  is too big: only global variables are needed.
- Works with recursively defined blocks with local variables (**how?**)
- Memory grows unbounded but  $\Sigma$  is bounded; we could remove useless locations (gc or manually),
- Have to deal with two levels for memory addressing but this is closer to reality (e.g. statements are not modified upon function call).
- **What is a good initial configuration?**

# An example

**Evaluate the following program:**

```
int x
int f(int x) {
  int y;
  x:=1;
  y:=2;
  return x+1;
}
{
  int y;
  x:=0;
  y:=0;
  y:=f(3);
}
```

## 1 Operational Semantics for functions

- Big-step semantics: first solution
- Big-step semantics: second solution
- Big-step semantics: third solution
- Small-step semantics based on third solution

## 2 Safety of the type-system

# Structural Op. Semantics (SOS = small step) for mini-while (OLD)

$$(x := a, \sigma) \Rightarrow \sigma[x \mapsto Val(a, \sigma)]$$

$$(\text{skip}, \sigma) \Rightarrow \sigma$$

$$\frac{(S_1, \sigma) \Rightarrow \sigma'}{((S_1; S_2), \sigma) \Rightarrow (S_2, \sigma')} \quad \frac{(S_1, \sigma) \Rightarrow (S'_1, \sigma')}{((S_1; S_2), \sigma) \Rightarrow (S'_1; S_2, \sigma')}$$

$$\frac{Val(b, \sigma) = tt}{(\text{if } b \text{ then } S_1 \text{ else } S_2, \sigma) \Rightarrow (S_1, \sigma)}$$

$$\frac{Val(b, \sigma) = ff}{(\text{if } b \text{ then } S_1 \text{ else } S_2, \sigma) \Rightarrow (S_2, \sigma)}$$

# OLD SOS with new store structure – Principle

New configuration:  $(Stm, ??, Stack, Store)$ .  $??$  defined later.

$$(x := e, ??, \Sigma, \mathbf{sto}) \Rightarrow (\Sigma, \mathbf{sto}[\Sigma(x) \mapsto \mathbf{Val}(e, \mathbf{sto} \circ \Sigma)])$$

$$(\text{skip}, ??, \Sigma, \mathbf{sto}) \Rightarrow (\Sigma, \mathbf{sto})$$

$$(S_1, ??, \Sigma, \mathbf{sto}) \Rightarrow (\Sigma', \mathbf{sto}')$$

$$\frac{(S_1, ??, \Sigma, \mathbf{sto}) \Rightarrow (\Sigma', \mathbf{sto}')}{((S_1; S_2), ??, \Sigma, \mathbf{sto}) \Rightarrow (S_2, ??, \Sigma', \mathbf{sto}')}$$

$$(S_1, ??, \Sigma, \mathbf{sto}) \Rightarrow (S'_1, ??, \Sigma', \mathbf{sto}')$$

$$\frac{(S_1, ??, \Sigma, \mathbf{sto}) \Rightarrow (S'_1, ??, \Sigma', \mathbf{sto}')}{((S_1; S_2), ??, \Sigma, \mathbf{sto}) \Rightarrow ((S'_1; S_2), ??, \Sigma', \mathbf{sto}')}$$

$$\mathbf{Val}(b, \mathbf{sto} \circ \Sigma) = tt$$

$$\frac{\mathbf{Val}(b, \mathbf{sto} \circ \Sigma) = tt}{(\text{if } b \text{ then } S_1 \text{ else } S_2, ??, \Sigma, \mathbf{sto}) \Rightarrow (S_1, ??, \Sigma, \mathbf{sto})}$$

$$\mathbf{Val}(b, \mathbf{sto} \circ \Sigma) = ff$$

$$\frac{\mathbf{Val}(b, \mathbf{sto} \circ \Sigma) = ff}{(\text{if } b \text{ then } S_1 \text{ else } S_2, ??, \Sigma, \mathbf{sto}) \Rightarrow (S_2, ??, \Sigma, \mathbf{sto})}$$

## Small step semantics, based on third solution

?? is used to remember the execution contexts: it is a list of  $(Stack, Stm)$ . Let  $::$  be the list constructor.  $Ctx$  is a list of  $(Stack, Stm)$ . In the big step semantics this is not needed because the inference is more complex (and remembers contexts)

CALL

$$\frac{bind_3(f, e_1..e_n, \Sigma, sto) = (S', \Sigma', sto')}{(x := f(e_1, .., e_n); S, Ctx, \Sigma, sto) \Rightarrow (S', (\Sigma, x := R(f); S) :: Ctx, \Sigma', sto')}$$

$x := f(e_1, .., e_n); S$  must be the whole current statement (imposed by the rule for sequence).  $R(f)$  is just a marker that remembers the name of the function called (and the calling point).

## SOS with new store structure and contexts

$$\begin{array}{c}
 (x := e, Ctx, \Sigma, \textcolor{green}{sto}) \Rightarrow (Ctx, \Sigma, \textcolor{green}{sto}[\Sigma(x) \mapsto \textcolor{green}{Val}(e, \textcolor{green}{sto} \circ \Sigma)]) \\
 \frac{(S_1, Ctx, \Sigma, \textcolor{green}{sto}) \Rightarrow (Ctx, \Sigma', \textcolor{green}{sto}')}{((S_1; S_2), Ctx, \Sigma, \textcolor{green}{sto}) \Rightarrow (S_2, Ctx, \Sigma', \textcolor{green}{sto}')} \\
 \frac{(S_1, Ctx, \Sigma, \textcolor{green}{sto}) \Rightarrow (S'_1, Ctx, \Sigma', \textcolor{green}{sto}')}{((S_1; S_2), Ctx, \Sigma, \textcolor{green}{sto}) \Rightarrow (S'_1; S_2, Ctx, \Sigma', \textcolor{green}{sto}')}
 \end{array}$$

And a new **rule** for return (when current computation finished)

$$\frac{v = \textcolor{green}{Val}(\textcolor{green}{ret}(f), \textcolor{green}{sto} \circ \Sigma')}{((\Sigma, x := R(f); S) :: Ctx, \Sigma', \textcolor{green}{sto}) \Rightarrow (S, Ctx, \Sigma, \textcolor{green}{sto}[\Sigma(x) \mapsto v])}$$

if, skip, and while rules are trivially adapted

**What do we have at the end of the execution? Initial configuration and global semantics on board**

# An example

**Evaluate the following program:**

```
int x
int f(int x) {
  int y;
  x:=1;
  y:=2;
  return x+1;
}
{
  int y;
  x:=0;
  y:=0;
  y:=f(3);
}
```

- 1 Operational Semantics for functions
- 2 Safety of the type-system

## [REMINDER] Safety = well typed programs do not go wrong

In case of a small-step semantics safety relies on two lemmas:

**Well-type programs run without error**

**Lemma (progression for mini-while)**

*If  $\Gamma \vdash (S, \sigma)$ , then there exists  $S', \sigma'$  such that  $(S, \sigma) \Rightarrow (S', \sigma')$   
OR there exists  $\sigma'$  such that  $(S, \sigma) \Rightarrow \sigma'$ .*

**... and remain well-typed**

**Lemma (preservation)**

*If  $\Gamma \vdash (S, \sigma)$  and  $(S, \sigma) \Rightarrow (S', \sigma')$  then  $\Gamma \vdash (S', \sigma')$ .*

Note:  $(S, \sigma)$  cannot be a final configuration.  $\Gamma$  never changes (defined by declarations)

Recall the property for expression evaluation: if  $\sigma$  and  $\Gamma$  agree on all variables the valuation of the expression is of the right type.

## [Reminder] Typing rules

Typing of statements has the form :  $\Gamma, \Gamma_f \vdash S$  Where  $\Gamma$ : map that defines the variable types,  $\Gamma_f$ : function map,  $S$  statement.

$$\begin{array}{c}
 D \rightarrow_d \Gamma_g \quad Fundef \rightarrow_f \Gamma_f \quad D_m \rightarrow_d \Gamma_m \\
 \Gamma_g + \Gamma_m, \Gamma_f \vdash S \quad \forall (\tau \ f(x_1 : \tau_1, \dots, x_n : \tau_n) \ D_f; S_f; \text{return } e \in Fundef). \\
 \Gamma_g + \Gamma_l \vdash e : \tau \wedge \Gamma_g + \Gamma_l, \Gamma_f \vdash S_f \text{ with } x_1 : \tau_1; \dots; x_n : \tau_n; D_f \rightarrow_d \Gamma_l \\
 \hline
 \vdash D \ Fundef \ D_m; S
 \end{array}$$

$\Gamma_g + \Gamma_l$  overrides  $\Gamma_g$  with  $\Gamma_l$ , i.e.  $(\Gamma_g + \Gamma_l)(x)$  is  $\Gamma_l(x)$  if it is defined and  $\Gamma_g(x)$  else.

CALL

$$\begin{array}{c}
 \Gamma_f(f) = \tau_1.. \tau_n \rightarrow \tau \quad \forall i \in [1..n]. \Gamma \vdash e_i : \tau_i \quad \Gamma \vdash x : \tau \\
 \hline
 \Gamma, \Gamma_f \vdash x := f(e_1, \dots, e_n)
 \end{array}$$

# State type safety and prove it for functions

Slight change in the correctness wrt store, it cannot be:

$$\Gamma \vdash (S, \sigma) \iff (\Gamma \vdash S \wedge \forall x. \emptyset \vdash \sigma(x) : \tau \iff \Gamma(x) = \tau)$$

any more!

**On board: adaptation of the thm + proof “sketch”**

## Conclusion

We had a look at many semantics to specify function behaviour; difficulty came from the imperative aspect + scopes + context switch.

Problems solved:

- stacking environment
- scope of variables
- restoring the right environment after invocation
- return a value

Each of the semantics has its advantages and corresponds to some of the semantics encountered in the literature.

We have not seen how to deal with imbricated scopes in general (it is often a simple extension along the same principles)

## Dealing with non-terminal return [bonus]

In big step semantics: One simple solution is to interrupt big step and get back to function call

$$\frac{v = Val(e, \Sigma)}{(return\ e, \Sigma) \longrightarrow (return\ v, \Sigma)}$$

Need to deal with sequence:

$$\frac{(S_1, \Sigma) \longrightarrow (return\ v, \Sigma')}{((S_1; S_2), \Sigma) \longrightarrow (return\ v, \Sigma')}$$

Strictly speaking this is not sufficient: **why?**

In practice a lot of rules become more complex

Using statement lists is often easier.
